Equipment Quality Improvement Verification Report

Verification scope and method

Document ID: HB-QA-2026-01 | Approval date: 2026.07.05 | Quality Management Team

Defect rates for April-June 2026 were examined after sensor calibration and improvements to work standards on Production Line 2. The pre-improvement baseline is January-March 2026.

The defect rate is the number of defective units divided by the number of units inspected. Round only for the final display. For an entire period, divide the total number of defective units by the total number of inspected units.

The source data is the C02 monthly inspection summary. Distinguish observing an improvement from confirming that it is sustained over the long term.

Equipment Quality Improvement Verification Report - continued

Inspection results

Period	Units inspected	Defective units	Defect rate
January-March 2026	30000	1140	3.8%
April-June 2026	30000	870	2.9%

The post-improvement defect rate is 2.9%. The difference from the pre-improvement rate is 0.9 percentage points. Because the same number of units was inspected each month, the average monthly rate and the rate for the entire period are equal in this dataset.

Sensor calibration and revisions to work standards were carried out on Production Line 2. Figures from other production lines were not included in this evaluation.

Interpretation and follow-up

A reduction in the defect rate was observed over the 3 months after the improvement. However, the long-term effect has not yet been confirmed; additional follow-up is needed in July-September 2026.

These data do not support stating that the long-term effect has been proven or deciding to skip additional checks.

Follow C03 for the follow-up plan. The Quality Management Team continues the monthly summaries, and the October review meeting determines whether the improvement has been sustained.
